Data structures (2)

HashMap.h
Description: Hash map with mostly the same API as unordered_map, but
~3x faster. Uses 1.5x memory. Initial capacity must be a power of 2 (if
provided). For PBDS swap(a,b) works in O(N), use a.swap(b) instead!
3e474b, 12 lines

#include <ext/pb_ds/assoc_container.hpp>
using namespace __gnu_pbds;
// for places where hacking might be a problem:
const int R = chrono::high_resolution_clock::
    now().time_since_epoch().count();
struct chash { // to use most bits rather than just the lowest
    const uint64_t C = 1l(4e18 * acos(0)) | 71;
    ll operator()(ll x) const {
        return __builtin_bswap64((x^R)*C); }
};
// 1<< 16 is initial size, don't put it if you want small map
gp_hash_table<ll, int, chash> h({}, {}, {}, {}, {1 << 16});

OrderStatisticTree.h
Description: A set (not multiset!) with support for finding the n'th ele-
ment, and finding the index of an element. To get a map, change null-type.
For PBDS swap(a,b) works in O(N), use a.swap(b) instead!
Time: O(log N), join probably O(N)
023ea1, 17 lines

#include <ext/pb_ds/assoc_container.hpp>
#include <ext/pb_ds/tree_policy.hpp>
using namespace __gnu_pbds;

template<class T>
```

```
using Tree = tree<T, null_type, less<T>, rb_tree_tag,
    tree_order_statistics_node_update>;

void example() {

        for (int pw = 1 << 25; pw; pw >>= 1) {
            if (pos + pw <= SZ(s) && s[pos + pw-1] < sum)
                pos += pw, sum -= s[pos-1];
        }
        return pos;
    }
};
```

### FenwickTree2D.h

**Description:** Computes sums  $a[i,j]$  for all  $i < I, j < J$ , and increases single elements  $a[i,j]$ . Requires that the elements to be updated are known in advance (call fakeUpdate() before init()).

**Time:**  $\mathcal{O}(\log^2 N)$  (use persistent segment trees for  $\mathcal{O}(\log N)$ )

"FenwickTree.h" cc92f9, 21 lines

```
struct FT2 {
    vector<vi> ys; vector<FT> ft;
    FT2(int limx) : ys(limx) {}
    void fakeUpdate(int x, int y) {
        for(; x < SZ(ys); x |= x + 1) ys[x].pb(y);
    }
    void init() {
        for(vi &v: ys) sort(all(v)), ft.emplace_back(SZ(v));
    }
    int ind(int x, int y) {
        return int(lower_bound(all(ys[x]), y) - ys[x].begin());
    }
    void update(int x, int y, ll dif) {
        for(; x < SZ(ys); x |= x + 1) ft[x].update(ind(x,y), dif);
    }
    ll query(int x, int y) {
        ll sum = 0;
        for(; x; x &= x - 1) sum += ft[x-1].query(ind(x-1, y));
        return sum;
    }
};
```

### PersistentSegmentTree.h

**Description:** Persistent structures use a lot of memory in general, so remember to optimise the code whenever possible. Push function is responsible for creating copies of children, so whenever we enter a vertex (either add or query) it's already a fresh copy. When there is no lazy, it's better to modify this approach, and only create a vertex when we really visit it, so we can save memory.

**Time:**  $\mathcal{O}(\log N)$  per operation

c5c0ae, 58 lines

```
struct PersistentTree {
    using T = ll; // persistency needs a lot of memory

FOR(j, 0, n) tmp[i][j] = tmp[i][j] * v % mod;
A[i][i] = 1;
}
per(i, 0, n-1) FOR(j, 0, i) {
    ll v = A[j][i];
    FOR(k, 0, n) tmp[j][k] = (tmp[j][k] - v*tmp[i][k]) % mod;
}
FOR(i, 0, n) FOR(j, 0, n) {
    A[col[i]][col[j]] = tmp[i][j] % mod +
        (tmp[i][j] < 0 ? mod : 0); }
return n;
}
```

Tridiagonal.h

**Description:**  $x = \text{tridiagonal}(d, p, q, b)$  solves the equation system

$$\begin{pmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ \vdots \\ b_{n-1} \end{pmatrix} = \begin{pmatrix} d_0 & p_0 & 0 & 0 & \cdots & 0 \\ q_0 & d_1 & p_1 & 0 & \cdots & 0 \\ 0 & q_1 & d_2 & p_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & q_{n-3} & d_{n-2} & p_{n-2} \\ 0 & 0 & \cdots & 0 & q_{n-2} & d_{n-1} \end{pmatrix} \begin{pmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_{n-1} \end{pmatrix}.$$

This is useful for solving problems on the type

$$a_i = b_i a_{i-1} + c_i a_{i+1} + d_i, 1 \leq i \leq n,$$

where  $a_0, a_{n+1}, b_i, c_i$  and  $d_i$  are known.  $a$  can then be obtained from

$$\{a_i\} = \text{tridiagonal}(\{1, -1, -1, \dots, -1, 1\}, \{0, c_1, c_2, \dots, c_n\}, \{b_1, b_2, \dots, b_n, 0\}, \{a_0, d_1, d_2, \dots, d_n, a_{n+1}\}).$$

Fails if the solution is not unique. If  $|d_i| > |p_i| + |q_{i-1}|$  for all  $i$ , or  $|d_i| > |p_{i-1}| + |q_i|$ , or the matrix is positive definite, the algorithm is numerically stable and neither `tr` nor the check for `diag[i] == 0` is needed.

**Time:**  $\mathcal{O}(N)$

```
736a43, 24 lines

using T = double;
vector<T> tridiagonal(vector<T> diag, const vector<T> &super,
    const vector<T> &sub, vector<T> b) {
    int n = SZ(b); vi tr(n);
    FOR(i, 0, n-1) {
        if(abs(diag[i]) < 1e-9 * abs(super[i])) { // diag[i] == 0
            b[i+1] -= b[i] * diag[i+1] / super[i];
            if(i+2 < n) b[i+2] -= b[i] * sub[i+1] / super[i];
            diag[i+1] = sub[i]; tr[++i] = 1; }
        else {
            diag[i+1] -= super[i]*sub[i]/diag[i];
            b[i+1] -= b[i]*sub[i]/diag[i]; }
    }

    }
    return b;
}
```

3.4 Fourier transforms

FastFourierTransform.h

**Description:**  $\text{fft}(a)$  computes  $\hat{f}(k) = \sum_x a[x] \exp(2\pi i \cdot kx/N)$  for all  $k$ .  $N$  must be a power of 2. Useful for convolution:  $\text{conv}(a, b) = c$ , where  $c[x] = \sum a[i]b[x-i]$ . For convolution of complex numbers or more than two vectors: FFT, multiply pointwise, divide by  $n$ , reverse(start+1, end), FFT back. Rounding is safe if  $(\sum a_i^2 + \sum b_i^2) \log_2 N < 9 \cdot 10^{14}$  (in practice  $10^{16}$ ; higher for random inputs). Otherwise, use NTT/FFTMod.

**Time:**  $\mathcal{O}(N \log N)$  with  $N = |A| + |B|$  ( $\sim 1s$  for  $N = 2^{22}$ )

87d73c, 32 lines

    }
};
```

### MillerRabin.h

**Description:** Deterministic Miller-Rabin primality test. Guaranteed to work for numbers up to  $7 \cdot 10^{18}$ ; for larger numbers, use Python and extend A randomly.

**Time:** 7 times the complexity of  $a^b \pmod c$ .

"ModMulLL.h"	3ba57b, 12 lines
--------------	------------------

```
bool isPrime(ull n) {
    if(n < 2 || n % 6 % 4 != 1) return (n | 1) == 3;
    ull A[] = {2, 325, 9375, 28178, 450775, 9780504, 1795265022},
        s = __builtin_ctzll(n-1), d = n >> s;
    for(ull a : A) { // ^ count trailing zeroes
        ull p = modpow(a%n, d, n), i = s;
        while(p != 1 && p != n - 1 && a % n && i--) {
            p = modmul(p, p, n);
            if(p != n-1 && i != s) return 0;
        }
        return 1;
    }
}
```

### Factor.h

**Description:** Pollard-rho randomized factorization algorithm. Returns prime factors of a number, in arbitrary order (e.g. 2299 -> {11, 19, 11}).

**Time:**  $\mathcal{O}\left(n^{1/4}\right)$ , less for numbers with small factors.

"ModMulLL.h", "MillerRabin.h"	d8d98d, 18 lines
-------------------------------	------------------

```
ull pollard(ull n) {
    ull x = 0, y = 0, t = 30, prd = 2, i = 1, q;
    auto f = [&](ull x) { return modmul(x, x, n) + i; };
    while(t++ % 40 || __gcd(prd, n) == 1) {
        if(x == y) x = ++i, y = f(x);
        if((q = modmul(prd, max(x,y) - min(x,y), n))) prd = q;
        x = f(x), y = f(f(y));
    }
    return __gcd(prd, n);
}

    l.insert(l.end(), all(r));
    return l;
}
```

## 4.3 Divisibility

### euclid.h

**Description:** Finds two integers  $x$  and  $y$ , such that  $ax + by = \gcd(a, b)$ . If you just need gcd, use the built in gcd instead. If  $a$  and  $b$  are coprime, then  $x$  is the inverse of  $a \pmod b$ .

	8d2423, 10 lines
--	------------------

```
ll euclid(ll a, ll b, ll &x, ll &y) {
    if(!b) return x = 1, y = 0, a;
    ll d = euclid(b, a % b, y, x);
    return y -= a / b * x, d;
}

ll modInv(ll a, ll mod) {
    ll inv, b; euclid(a, mod, inv, b); inv %= mod;
    return inv < 0 ? inv + mod : inv;
}
```

### CRT.h

**Description:** Chinese Remainder Theorem.

crt(a, m, b, n) computes  $x$  such that  $x \equiv a \pmod m, x \equiv b \pmod n$ . If  $|a| < m$  and  $|b| < n$ ,  $x$  will obey  $0 \leq x < \text{lcm}(m, n)$ . Assumes  $mn < 2^{62}$ .

**Time:** log( $n$ )

"euclid.h"	04d93a, 7 lines
------------	-----------------

```
ll crt(ll a, ll m, ll b, ll n) {
    if(n > m) swap(a, b), swap(m, n);
    ll x, y, g = euclid(m, n, x, y);
    assert((a - b) % g == 0); // else no solution
    x = (b - a) % n * x % n / g * m + a;
    return x < 0 ? x + m * n / g : x;
}
```

## 4.4 Other

### FracBinarySearch.h

**Description:** Given  $f$  and  $N$ , finds the smallest fraction  $p/q \in [0, 1]$  such that  $f(p/q)$  is true, and  $p, q \leq N$ . You may want to throw an exception from  $f$  if it finds an exact solution, in which case  $N$  can be removed.

**Usage:** fracBS([](Frac f) { return f.p>=3\*f.q; }, 10); // {1,3}

**Time:**  $\mathcal{O}(\log(N))$

	27ab3e, 21 lines
--	------------------

```
struct Frac { ll p, q; };
```

```
template<class F>
```

```
Frac fracBS(F f, ll N) {
```

```
bool dir = 1, A = 1, B = 1;
Frac lo{0, 1}, hi{1, 1}; // Set hi to 1/0 to search (0, N]
if (f(lo)) return lo;
assert(f(hi));
while(A || B) {
  ll adv = 0, step = 1; // move hi if dir, else lo
  for(int si = 0; step; (step *= 2) >= si) {
    adv += step;
    Frac mid{lo.p * adv + hi.p, lo.q * adv + hi.q};
    if(abs(mid.p) > N || mid.q > N || dir == !f(mid)) {
      adv -= step; si = 2; }
  }
  hi.p += lo.p * adv; hi.q += lo.q * adv; dir = !dir;
  swap(lo, hi); A = B; B = !!adv;
}
return dir ? hi : lo;
}
```

**PrefixSumMultiplicative.h**  
**Description:** Computes prefix sum  $F(x)$  of multiplicative function  $f(x)$  using Dirichlet inverse. To use it you need to find such a function  $g(x)$ , that for  $c(x) = (f * g)(x)$  being their Dirichlet convolution,  $G(x)$  and  $C(x)$  can be quickly calculated. As  $F(x)$  is multiplicative, standard trick is to compute small values using linear sieve. Provided  $F(x)$  should work for  $x < th$ ,  $G(x)$  and  $C(x)$  should work for  $x \leq N$ . Threshold  $th$  should be  $\sim N^{\frac{2}{3}}$  (for single query). Hashmap can be changed to simple array (for single query), use  $\frac{x}{t}$  as "hash function".  
**Time:**  $\mathcal{O}\left(N^{\frac{2}{3}}\right)$

```
struct PrefSumMul {
  function<ll(ll)> F, G, C; ll th;
  unordered_map<ll, ll> mem;
  PrefSumMul(auto _F, auto _G, auto _C, ll _th) :
    F(_F), G(_G), C(_C), th(_th) {}
  ll calc(ll x) {
    if(x < th) return F(x);
    auto d = mem.find(x); if(d != mem.end()) return d->nd;
    ll res = 0;
    for(ll i = 2, la; i <= x; i = la + 1) {
      la = x / (x / i); // largest with same value
      res = (res + (G(la) - G(i-1) + mod) * calc(x/i)) % mod;
    } // if G(1) != 1 then use modInv there
    return mem[x] = (C(x) - res + mod) / G(1) % mod;
  }
};
```

4.5 Pythagorean Triples

The Pythagorean triples are uniquely generated by

$a = k \cdot (m^2 - n^2), \quad b = k \cdot (2mn), \quad c = k \cdot (m^2 + n^2),$

with  $m > n > 0, k > 0, m \perp n$ , and either  $m$  or  $n$  even.

4.6 Mobius Function

$$\mu(n) = \begin{cases} 0 & n \text{ is not square free} \\ 1 & n \text{ has even number of prime factors} \\ -1 & n \text{ has odd number of prime factors} \end{cases}$$

Mobius Inversion:

$$g(n) = \sum_{d|n} f(d) \Leftrightarrow f(n) = \sum_{d|n} \mu(d)g(n/d)$$

Other useful formulas/forms:

PrefixSumMultiplicative

$$\sum_{d|n} \mu(d) = [n = 1] \text{ (very useful)}$$
$$g(n) = \sum_{n|d} f(d) \Leftrightarrow f(n) = \sum_{n|d} \mu(d/n)g(d)$$
$$g(n) = \sum_{1 \leq m \leq n} f(\lfloor \frac{n}{m} \rfloor) \Leftrightarrow f(n) = \sum_{1 \leq m \leq n} \mu(m)g(\lfloor \frac{n}{m} \rfloor)$$

Combinatorial (5)

5.1 Permutations

5.1.1 Burnside’s lemma

Given a group  $G$  of symmetries and a set  $X$ , the number of elements of  $X$  up to symmetry equals

$$\frac{1}{|G|} \sum_{g \in G} |X^g|,$$

where  $X^g$  are the elements fixed by  $g$  ( $g.x = x$ ).

If  $f(n)$  counts “configurations” (of some sort) of length  $n$ , we can ignore rotational symmetry using  $G = \mathbb{Z}_n$  to get

$$g(n) = \frac{1}{n} \sum_{k=0}^{n-1} f(\gcd(n, k)) = \frac{1}{n} \sum_{k|n} f(k)\phi(n/k).$$

5.1.2 Young diagram

Given a partition  $\lambda$ , the Young diagram  $Y(\lambda)$  is the set of pairs  $(i, j)$  of positive integers s.t.  $i \leq |\lambda|$  and  $j \leq \lambda_i$ . Such pairs are called the squares of the diagram.

A normalised Young tableau  $P$  of size  $n$  is a pair  $(\lambda, p)$ , where  $p$  is a permutation indexed by  $Y(\lambda)$  s.t.  $p_{i,j} < \min(p_{i+1,j}, p_{i,j+1})$ .

There is a bijection  $f$  from permutations  $\pi$  of length  $n$  to pairs  $(P, Q) = ((\lambda, p), (\lambda, q))$  of Young tableaux of size  $n$ , which share the same partition.

This mapping (which can be computed by RSK) has the following properties:

- $\sum_{i \leq m} \lambda_i$  is the maximum total size of  $m$  disjoint **increasing** subsequences of the permutation
- $\sum_{j \leq m} \lambda_j^T$  is the maximum total size of  $m$  disjoint **decreasing** subsequences of the permutation
- $f(\pi^{-1}) = (Q, P)$
- $f(\text{rev}(\pi)) = (P^T, \text{Sch}(Q)) - \text{Sch}$  is the normalised result of the Schützenberger involution

If  $c(\lambda)$  is the number of valid  $p$  for the partition  $\lambda$ , then  $n! = \sum_{\lambda \in P_n} c(\lambda)^2$ .  
The number of permutations s.t.  $\pi = \pi^{-1}$  is  $\sum_{\lambda \in P_n} c(\lambda)$ .

5.1.3 Hook-length formula

For  $\lambda \in P_n$  and  $(i, j) \in Y(\lambda)$ , define  $h_\lambda(i, j)$  as the number of squares in the diagram directly below or to the right of square  $(i, j)$ :  $h_\lambda(i, j) = (\lambda_j^T - i) + (\lambda_i - j) + 1$ .

The hook-length theorem states that:

$$c(\lambda) = \frac{n!}{\prod_{(i,j) \in Y(\lambda)} h_\lambda(i, j)}$$

5.2 General purpose numbers

5.2.1 Bernoulli numbers

EGF of Bernoulli numbers is  $B(t) = \frac{t}{e^t - 1}$  (FFT-able).  
 $B[0, \dots] = [1, -\frac{1}{2}, \frac{1}{6}, 0, -\frac{1}{30}, 0, \frac{1}{42}, \dots]$

Sums of powers:

$$\sum_{i=1}^n n^m = \frac{1}{m+1} \sum_{k=0}^m \binom{m+1}{k} B_k \cdot (n+1)^{m+1-k}$$

Euler-Maclaurin formula for infinite sums:

$$\sum_{i=m}^\infty f(i) = \int_m^\infty f(x)dx - \sum_{k=1}^\infty \frac{B_k}{k!} f^{(k-1)}(m)$$
$$\approx \int_m^\infty f(x)dx + \frac{f(m)}{2} - \frac{f'(m)}{12} + \frac{f'''(m)}{720} + O(f^{(5)}(m))$$

5.2.2 Stirling numbers of the first kind

Number of permutations on  $n$  items with  $k$  cycles.

$$c(n, k) = c(n - 1, k - 1) + (n - 1)c(n - 1, k), \quad c(0, 0) = 1$$
$$\sum_{k=0}^n c(n, k)x^k = x(x + 1) \dots (x + n - 1)$$

$c(8, k) = 8, 0, 5040, 13068, 13132, 6769, 1960, 322, 28, 1$   
 $c(n, 2) = 0, 0, 1, 3, 11, 50, 274, 1764, 13068, 109584, \dots$

5.2.3 Eulerian numbers

Number of permutations  $\pi \in S_n$  in which exactly  $k$  elements are greater than the previous element.  $k$   $j$ :s s.t.  $\pi(j) > \pi(j + 1)$ ,  $k + 1$   $j$ :s s.t.  $\pi(j) \geq j$ ,  $k$   $j$ :s s.t.  $\pi(j) > j$ .

$$E(n, k) = (n - k)E(n - 1, k - 1) + (k + 1)E(n - 1, k)$$

$$E(n, 0) = E(n, n - 1) = 1$$

$$E(n, k) = \sum_{j=0}^k (-1)^j \binom{n+1}{j} (k+1-j)^n$$

5.2.4 Stirling numbers of the second kind

Partitions of  $n$  distinct elements into exactly  $k$  groups.

$$S(n, k) = S(n - 1, k - 1) + kS(n - 1, k)$$

$$S(n, 1) = S(n, n) = 1$$

$$S(n, k) = \frac{1}{k!} \sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n$$

### 5.2.5 Bell numbers

Total number of partitions of  $n$  distinct elements.  $B(n) = 1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, \dots$  For  $p$  prime,

$$B(p^m + n) \equiv mB(n) + B(n+1) \pmod{p}$$

### 5.2.6 Labeled unrooted trees

# on  $n$  vertices:  $n^{n-2}$

# on  $k$  existing trees of size  $n_i$ :  $n_1 n_2 \dots n_k n^{k-2}$

# with degrees  $d_i$ :  $(n-2)! / ((d_1-1)! \dots (d_n-1)!)$

### RSK.h

**Description:** Computes mapping from permutations to pairs of normalised Young diagrams (Robinson-Schensted correspondence). Properties of this mapping are described in Young diagram section.

**Time:**  $\mathcal{O}(N\sqrt{N}\log N)$

08bec9, 24 lines

```
vector<vi> boundedRSK(vi pi, int k) {
    vector<vi> res;
    for(auto x: pi) FOR(j, 0, k) {
        if(j >= SZ(res)) res.pb({});
        int pos = lower_bound(all(res[j]), x) - res[j].begin();
        if(pos == SZ(res[j])) { res[j].pb(x); break; }
        swap(x, res[j][pos]);
    }
    return res;
}
```

```
pair<vector<vi>, vector<vi>> fastRSK(vi pi) {

```

6.3 DFS algorithms  
BiconnectedComponents.h  
Description: Finds all biconnected components in an undirected graph, and runs a callback for the edges in each. In a biconnected component there are at least two distinct paths between any two nodes. Note that a node can be in several components. An edge which is not in a component is a bridge, i.e., not part of any cycle.  
Usage: int eid = 0; ed.resize(N);  
for each edge (a,b) {  
 ed[a].emplace\_back(b, eid);  
 ed[b].emplace\_back(a, eid++); }  
bicomps([&](const vi& edgelist) {...});  
Time:  $\mathcal{O}(E + V)$

43b75d, 30 lines

```
vi num, st;
vector<vector<pii>> ed;
int Time;
template<class F>
int dfs(int at, int par, F& f) {
    int me = num[at] = ++Time, top = me;
    for(auto [y, e]: ed[at]) if(e != par) {
        if(num[y]) {
            top = min(top, num[y]);
            if(num[y] < me) st.pb(e); }
        else {
            int si = SZ(st), up = dfs(y, e, f);
            top = min(top, up);
            if(up == me) {
                st.pb(e);
                f(vi(st.begin() + si, st.end()));
                st.resize(si);
            }
            else if(up < me) st.pb(e);

        }
    }
    return top;
}
```

```
template<class F>
void bicomps(F f) {
    num.assign(SZ(ed), 0);
    FOR(i, 0, SZ(ed)) if(!num[i]) dfs(i, -1, f);
}
```

2sat.h  
Description: Calculates a valid assignment to boolean variables a, b, c,... to a 2-SAT problem, so that an expression of the type  $(a \vee b) \wedge (a \vee c) \wedge (d \vee b) \wedge \dots$  becomes true, or reports that it is unsatisfiable. Negated variables are represented by bit-inversions (~x).  
Usage: TwoSat ts(number of boolean variables);  
ts.either(0, ~3); // Var 0 is true or var 3 is false  
ts.setValue(2); // Var 2 is true  
ts.atMostOne({0,~1,2}); //  $\leq 1$  of vars 0, ~1 and 2 are true  
ts.solve(); // Returns true iff it is solvable  
ts.values[0..N-1] holds the assigned values to the vars  
Time:  $\mathcal{O}(N + E)$ , where N is the number of boolean variables, and E is the number of clauses.

EulerWalk.h  
**Description:** Eulerian undirected/directed path/cycle algorithm. Input should be a vector of (dest, global edge index), where for undirected graphs, forward/backward edges have the same index. Returns a list of nodes in the Eulerian path/cycle with src at both start and end, or empty list if no cycle/path exists. To get edge indices back, add .second to s and ret.  
**Time:**  $O(V + E)$

```
ecaa22, 12 lines
vi eulerWalk(vector<vector<pii>> &gr, int nedges, int src=0) {
    int n = SZ(gr); vi D(n), its(n), eu(nedges), ret, s = {src};
    D[src]++; // to allow Euler paths, not just cycles
    while(!s.empty()) {
        int x = s.back(), y, e, &it = its[x], end = SZ(gr[x]);
        if(it == end) { ret.pb(x); s.pop_back(); continue; }

    return {ret.rbegin(), ret.rend()};
}
```

6.4 Trees  
HLD.h

```
EulerWalk HLD CentroidTree LinkCutTree

Description: Decomposes a tree into vertex disjoint heavy paths and light edges such that the path from any leaf to the root contains at most log(n) light edges. Code does additive modifications and max queries, but can support commutative segtree modifications/queries on paths and subtrees. Takes as input the full adjacency list. VALS.EDGES being true means that values are stored in the edges, as opposed to the nodes. All values initialized to the segtree default. Root must be 0.  
Time:  $O((\log N)^2)$ 
ab0cb2, 32 lines

```

6.6 Math

6.6.1 Number of Spanning Trees

Create an  $N \times N$  matrix  $\text{mat}$ , and for each edge  $a \rightarrow b \in G$ , do  $\text{mat}[a][b]--$ ,  $\text{mat}[b][b]++$  (and  $\text{mat}[b][a]--$ ,  $\text{mat}[a][a]++$  if  $G$  is undirected). Remove the  $i$ th row and column and take the determinant; this yields the number of directed spanning trees rooted at  $i$  (if  $G$  is undirected, remove any row/column).

6.6.2 Erdős–Gallai theorem

A simple graph with node degrees  $d_1 \geq \dots \geq d_n$  exists iff  $d_1 + \dots + d_n$  is even and for every  $k = 1 \dots n$ :  $\sum_{i=1}^k d_i \leq k(k-1) + \sum_{i=k+1}^n \min(d_i, k)$ .

6.6.3 Markov chains

A *Markov chain* is a discrete random process with the property that the next state depends only on the current state. Let  $X_1, X_2, \dots$  be a sequence of random variables generated by the Markov process. Then there is a transition matrix  $\mathbf{P} = (p_{ij})$ , with  $p_{ij} = \Pr(X_n = i | X_{n-1} = j)$ , and  $\mathbf{p}^{(n)} = \mathbf{P}^n \mathbf{p}^{(0)}$  is the probability distribution for  $X_n$  (i.e.,  $p_i^{(n)} = \Pr(X_n = i)$ ), where  $\mathbf{p}^{(0)}$  is the initial distribution.

$\pi$  is a stationary distribution if  $\pi = \pi \mathbf{P}$ . If the Markov chain is *irreducible* (it is possible to get to any state from any state), then  $\pi_i = \frac{1}{\mathbb{E}(T_i)}$  where  $\mathbb{E}(T_i)$  is the expected time between two visits in state  $i$ .  $\pi_j / \pi_i$  is the expected number of visits in state  $j$  between two visits in state  $i$ .

For a connected, undirected and non-bipartite graph, where the transition probability is uniform among all neighbors,  $\pi_i$  is proportional to node  $i$ 's degree.

A Markov chain is *ergodic* if the asymptotic distribution is independent of the initial distribution. A finite Markov chain is ergodic iff it is irreducible and *aperiodic* (i.e., the gcd of cycle lengths is 1).  $\lim_{k \rightarrow \infty} \mathbf{P}^k = \mathbf{1}\pi$ .

A Markov chain is an A-chain if the states can be partitioned into two sets  $\mathbf{A}$  and  $\mathbf{G}$ , such that all states in  $\mathbf{A}$  are absorbing ( $p_{ii} = 1$ ), and all states in  $\mathbf{G}$  leads to an absorbing state in  $\mathbf{A}$ . The probability for absorption in state  $i \in \mathbf{A}$ , when the initial state is  $j$ , is  $a_{ij} = p_{ij} + \sum_{k \in \mathbf{G}} a_{ik} p_{kj}$ . The expected time until absorption, when the initial state is  $i$ , is  $t_i = 1 + \sum_{k \in \mathbf{G}} p_{ki} t_k$ .

```

lineDistance.h

```
Description:
Returns the signed distance between point p and the line containing points a and b. Positive value on left side and negative on right as seen from a towards b. a==b gives nan. P is supposed to be Point<T> or Point3D<T> where T is e.g. double or long long. It uses products in intermediate steps so watch out for overflow if using int or long long. Using Point3D will always give a non-negative distance. For Point3D, call .dist on the result of the cross product.
"Point.h"
0052e6, 4 lines

template<class P>
D lineDist(const P &a, const P &b, const P &p) {
    return (D)(b-a).cross(p-a)/(b-a).dist();
}
```

SegmentDistance.h

```
Description:
Returns the shortest distance between point p and the line segment from point s to e.
Usage: Point<D> a, b(2,2), p(1,1);
bool onSegment = segDist(a,b,p) < 1e-10;

    return q0 + P((r-p0).cross(num), (r-p0).dot(num))/dp.dist2();
}
```

### LineProjectionReflection.h

**Description:** Projects point p onto line ab. Set refl=true to get reflection of point p across line ab instead. The wrong point will be returned if P is an integer point and the desired point doesn't have integer coordinates. Products of three coordinates are used in intermediate steps so watch out for overflow.

```

"Point.h"
b5562d, 5 lines
```

```

template<class P>
P lineProj(P a, P b, P p, bool refl = false) {
    P v = b - a;
    return p - v.perp()*(1+refl)*v.cross(p-a)/v.dist2();
}
```

## 7.2 Circles

### CircleIntersection.h

**Description:** Computes the pair of points at which two circles intersect. Returns false in case of no intersection.

```

"Point.h"
9dd9e4, 11 lines

using P = Point<D>;
bool circleInter(P a, P b, D r1, D r2, pair<P, P>* out) {
    if(a == b) { assert(r1 != r2); return 0; }
    P vec = b - a;
    D d2 = vec.dist2(), sum = r1+r2, dif = r1-r2,
        p = (d2 + r1*r1 - r2*r2)/(d2*2), h2 = r1*r1 - p*p*d2;
    if (sum*sum < d2 || dif*dif > d2) return 0;
    P mid = a + vec*p, per = vec.perp() * sqrt(fmax(0, h2) / d2);
    *out = {mid - per, mid + per};
    return 1;
}
```

### CircleTangents.h

**Description:** Finds the external tangents of two circles, or internal if r2 is negated. Can return 0, 1, or 2 tangents – 0 if one circle contains the other (or overlaps it, in the internal case, or if the circles are the same); 1 if the circles are tangent to each other (in which case .first = .second and the tangent line is perpendicular to the line between the centers). .first and .second give the tangency points at circle 1 and 2 respectively. To find the tangents of a circle with a point set r2 to 0.

```

"Point.h"
c6361c, 13 lines

template<class P>
vector<pair<P, P>> tangents(P c1, D r1, P c2, D r2) {
    P d = c2 - c1;
    D dr = r1 - r2, d2 = d.dist2(), h2 = d2 - dr * dr;
    if(d2 == 0 || h2 < 0) return {};
    vector<pair<P, P>> out;

**Description:** Returns the two points with max distance on a convex hull (ccw, no duplicate/collinear points).  
**Time:**  $\mathcal{O}(n)$

"Point.h"	2aeca8, 11 lines
<pre> using P = Point&lt;ll&gt;; array&lt;P, 2&gt; hullDiameter(vector&lt;P&gt; S) {     int n = SZ(S), j = n &lt; 2 ? 0 : 1;     pair&lt;ll, array&lt;P, 2&gt;&gt; res({0, {S[0], S[0]}});     FOR(i, 0, j) for(;; j = (j + 1) % n) {         res = max(res, {{S[i] - S[j]}.dist2(), {S[i], S[j]}});         if((S[(j + 1) % n] - S[j]).cross(S[i + 1] - S[i]) &gt;= 0)             break;     }     return res.nd; }</pre>	

MinkowskiSum.h

**Description:** Computes the Minkowski sum of two convex polygons. Distance between two convex polygons can be computed by finding the closest edge of P - Q to the origin.

**Time:**  $\mathcal{O}(N)$

"Point.h"	d461a3, 14 lines
<pre> template&lt;class P&gt; vector&lt;P&gt; minkowski(vector&lt;P&gt; a, vector&lt;P&gt; b) {     rotate(a.begin(), min_element(all(a)), a.end());     rotate(b.begin(), min_element(all(b)), b.end());     FOR(i, 0, 2) a.pb(a[i]), b.pb(b[i]);     vector&lt;P&gt; res;     for(int i = 0, j = 0; i &lt; SZ(a) - 2    j &lt; SZ(b) - 2; ) {         res.pb(a[i] + b[j]);         auto cross = (a[i + 1] - a[i]).cross(b[j + 1] - b[j]);         if(cross &gt;= 0 &amp;&amp; i &lt; SZ(a)) i++;         if(cross &lt;= 0 &amp;&amp; j &lt; SZ(b)) j++;     }     return res; }</pre>	

PointInsideHull.h

**Description:** Determine whether a point t lies inside a convex hull (CCW order, with no collinear points). Returns true if point lies within the hull. If strict is true, points on the boundary aren't included.

**Time:**  $\mathcal{O}(\log N)$

"Point.h", "sideOf.h", "OnSegment.h"	550f0d, 13 lines
--------------------------------------	------------------

```

using P = Point<ll>;
bool inHull(const vector<P> &l, P p, bool strict = true) {
    int a = 1, b = SZ(l) - 1, r = !strict;
```

```
if(SZ(l) < 3) return r && onSegment(l[0], l.back(), p);
if(sideOf(l[0], l[a], l[b]) > 0) swap(a, b);
if(sideOf(l[0], l[a], p) >= r || sideOf(l[0], l[b], p) <= -r)
    return 0;
while(abs(a - b) > 1) {
    int c = (a + b) / 2;
    (sideOf(l[0], l[c], p) > 0 ? b : a) = c;
}
return sgn(l[a].cross(l[b], p)) < r;
}
```

## LineHullIntersection.h

**Description:** Line-convex polygon intersection. The polygon must be ccw and have no collinear points. lineHull(line, poly) returns a pair describing the intersection of a line with the polygon:  $\bullet(-1, -1)$  if no collision,  $\bullet(i, -1)$  if touching the corner  $i$ ,  $\bullet(i, i)$  if along side  $(i, i+1)$ ,  $\bullet(i, j)$  if crossing sides  $(i, i+1)$  and  $(j, j+1)$ . In the last case, if a corner  $i$  is crossed, this is treated as happening on side  $(i, i+1)$ . The points are returned in the same order as the line hits the polygon. extrVertex returns the point of a hull with the max projection onto a line.

**Time:**  $\mathcal{O}(\log n)$

"Point.h" e112e1, 39 lines

```
#define cmp(i, j) sgn(dir.perp().cross(poly[(i)%n]-poly[(j)%n]))

};
```

### sphericalDistance.h

**Description:** Returns the shortest distance on the sphere with radius  $r$ -adius from the points with azimuthal angles (longitude)  $f_1$  ( $\phi_1$ ) and  $f_2$  ( $\phi_2$ ) from  $x$  axis and zenith angles (latitude)  $t_1$  ( $\theta_1$ ) and  $t_2$  ( $\theta_2$ ) from  $z$  axis (0 = north pole). All angles measured in radians. The algorithm starts by converting the spherical coordinates to cartesian coordinates so if that is what you have you can use only the two last rows.  $dx$ \*radius is then the difference between the two points in the  $x$  direction and  $d$ \*radius is the total distance between the points.

232b64, 8 lines

```
using D = double;
D sphericalDistance(D f1, D t1, D f2, D t2, D radius) {
    D dx = sin(t2) * cos(f2) - sin(t1) * cos(f1);
    D dy = sin(t2) * sin(f2) - sin(t1) * sin(f1);
    D dz = cos(t2) - cos(t1);
    D d = sqrt(dx * dx + dy * dy + dz * dz);
    return radius * 2 * asin(d/2);
}
```

### SpheresIntersection.h

**Description:** Computes the intersection points of 3 spheres.

"Point3D.h" 738a7f, 17 lines

```

```
while((cnt % 2) != (x + y) % 2) cnt++;
if(x == 1 && !y) return 3;
if(y == 1 && !x) return 3;
if(x == y && x == 2) return 4;
return cnt;
}
```

9.2 Optimization tricks

9.2.1 Bit hacks

- $x \& -x$  is the least bit in x.
- `for(int x = m; x; ) { --x &= m; ... }` loops over all subset masks of m (except m itself).
- `c = x&-x, r = x+c; ((r^x) >> 2)/c | r` is the next number after x with the same number of bits set.
- `FOR(b, 0, K) FOR(i, 0, (1 << K))`  
    `if(i & 1 << b) D[i] += D[i^(1 << b)];`  
computes all sums of subsets.
